BLOGGING & PUBLISHING PLATFORM

User Stories & Acceptance Criteria

Reader, author and admin stories with acceptance criteria for Blog Hub.

Document BlogHub-US-001

Version v1.0

Author Irham Saleha

Prepared for Blog Hub project documentation

1. READER

As a reader, I want to read an article without signing up, so that nothing stands between me and the content.

- Given a published article URL, when opened signed out, then the full article renders with no prompt or overlay.
- Given the URL is shared, when someone else opens it, then they see the same complete article.

As a reader, I want to browse by category, so that I can find more of what I already like.

- Given a category page, when it loads, then published articles in that category appear newest first with pagination.
- Given a category holds no published articles, then the page explains that rather than rendering empty.

2. AUTHOR

As an author, I want to draft and preview before publishing, so that I can see exactly what a reader will see.

- Given an open draft, when previewed, then the rendering matches the published article view.
- Given the editor is left and reopened, then unsaved work has been retained as a draft.

As an author, I want to submit a post for review, so that an editor can approve it before it goes live.

- Given a draft, when submitted, then its state becomes in review and it appears in the admin queue.
- Given a post is in review, when direct publishing is attempted, then the transition is refused with an explanation.

As an author, I want to see how a post performed, so that I know what to write next.

- Given published posts, when the dashboard is opened, then views and comment counts are shown per post.

3. ADMIN

As an admin, I want a moderation queue, so that comments are handled in one place.

- Given a comment from a first-time commenter, when submitted, then it is held pending and is not publicly visible.
- Given a comment is approved or rejected, then the action, actor and time are written to the audit log.

As an admin, I want to manage roles, so that permissions match responsibility.

- Given a user, when their role is changed, then their access changes on their next request without needing a redeployment.
- Given an author is removed, then their published articles remain live under a retained attribution record.
